

TASK MANAGEMENT METHOD, TASK MANAGEMENT DEVICE, SEMICONDUCTOR
INTEGRATED CIRCUIT, ELECTRONIC APPARATUS, AND TASK MANAGEMENT
SYSTEM

5 BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates to a method for managing tasks to
be executed by a processor, a device for managing tasks by
10 using the method, a semiconductor integrated circuit as a
materialization of the device, and an electronic apparatus
having the semiconductor integrated circuit.

2. Description of the Related Art

With increasing trends toward finer manufacturing
15 processes and higher device integration, it has become
extremely important for LSI design to take account of the
amount of heat generation as chips' performance limits. At
higher temperatures, chips can malfunction or drop in long-
term reliability. Various measures against heat generation
20 have thus been taken. For example, in one method, radiating
fins are arranged on the top of a chip so as to release heat
occurring from the chip.

It has also been contemplated to schedule processor tasks
based on the distribution of power consumption on the chip.
25 Moreover, as a method of avoiding high chip temperatures,

studies have also been made to lower the operating frequency of the processor (for example, see US Patent Application Publication No. 2002/0065049).

While the operating frequency can be lowered to reduce the amount of heat generation in the chip, the reduced number of processing steps per unit time sometimes makes it impossible for tasks that must be completed within a unit time to be completed within a unit time. For this reason, programs must be designed on the basis of a minimum operating frequency in advance. This in turn makes it impossible to make full use of the processor throughput.

SUMMARY OF THE INVENTION

The present invention has been achieved in view of the foregoing problem and relates to an effective method for task management, a task management device based on the method, a semiconductor integrated circuit as a materialization of the device, and an electronic apparatus having the semiconductor integrated circuit to attain such conflicting goals.

One embodiment of the present invention relates to a method of executing tasks. This method includes dividing a unit time of processing in executing tasks by a processor into a reserved band for guaranteeing real-timeness and a non-reserved band not for guaranteeing real-timeness, and skipping

a task to be executed in the non-reserved band as appropriate when the processor falls in throughput. In the strict sense, executing a task or skipping a task refers to executing or skipping a process, or program, pertaining to the task. For
5 the sake of simplicity, however, such simple expressions as "executing a task" and "skipping a task" will be employed hereinafter. The term "task" shall refer to a single block of functions irrespective of the volume of the program. Thus, a task may sometimes refer to a functional unit greater than
10 ones recognized by actually-prevailing OSes.

"A fall in the throughput of the processor" may result from a decrease in the operating frequency of the processor. The operating frequency of the processor may be lowered when the processor or a peripheral circuit thereof exceeds a
15 predetermined threshold in temperature. The operating frequency may also be lowered depending on the power consumption of the processor.

According to this embodiment, tasks to be executed in the non-reserved band are skipped as appropriate when the
20 processor falls in throughput. Consequently, the real-timeness of tasks to be executed in the reserved band is guaranteed, or at least the probability thereof is increased significantly (hereinafter, referred to simply as "guaranteed"). In other words, as long as tasks to guarantee real-timeness of are
25 designed to fall within the reserved band, the throughput of

the processor may be changed without sinking below the reserved band. This allows flexible heat control on the processor.

Another embodiment of the present invention is a task management device. This device comprises: a switch instruction unit which issues an instruction to switch a plurality of tasks to be executed by a processor; and a detection unit which detects a throughput of the processor. The switch instruction unit divides a unit time of processing into a reserved band for guaranteeing real-timeness and a non-reserved band not for guaranteeing real-timeness, and skips a task to be executed in the non-reserved band as appropriate when the processor falls in throughput.

This device may further comprise an interpretation unit which interprets a requirement pertaining to real-timeness written in programs executed by the respective tasks. In this case, the switch instruction unit may allocate each of the tasks to either the reserved band or the non-reserved band based on the interpretation. For example, the "requirement pertaining to real-timeness" may be information available to determine whether or not to execute the tasks in the reserved band. It may also be information indicating attributes written in the programs or information showing the significances or priorities of the tasks.

This device may further comprise a determination unit by

which the processor determines properties of the programs executed by the respective tasks. In this case, the switch instruction unit may allocate each of the tasks to either the reserved band or the non-reserved band based on the

5 determination. The "property of a program" may be an instruction called from the program, the rate or time of occupation of the processor by the program, or a characteristic obtained indirectly by executing the task.

Another embodiment of the present invention is a task
10 management system. This system comprises: a processor which executes tasks at a predetermined operating frequency; a clock generation unit which supplies a clock having the operating frequency to the processor; and a switch instruction unit which issues an instruction to switch a plurality of tasks to
15 be executed by the processor. The switch instruction unit divides a unit time of processing into a reserved band for guaranteeing real-timeness and a non-reserved band not for guaranteeing real-timeness, and skips a task to be executed in the non-reserved band as appropriate when the operating
20 frequency of the processor falls.

Incidentally, any combinations of the foregoing components, and any conversions of expressions of the present invention from/into methods, apparatuses, systems, computer programs, and the like are also intended to constitute
25 applicable aspects of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments will now be described, by way of example only, with reference to the accompanying drawings which are meant to
5 be exemplary, not limiting, and wherein like elements are numbered alike in several Figures, in which:

Fig. 1A is a diagram showing in a time-series fashion the state of processing of tasks by a processor which operates at a normal operating frequency, Fig. 1B is a diagram showing in
10 a time-series fashion the state of processing of tasks by the processor at a lower operating frequency, and Fig. 1C is a diagram showing in a time-series fashion the state of processing of tasks by the processor at an even lower operating frequency;

15 Fig. 2A is a diagram showing the state of execution of tasks at an operating frequency of f_0 , i.e., at the normal operating frequency where the heat generation of the processor need not be suppressed, Fig. 2B is a diagram showing the state of execution of tasks at an operating frequency of $0.7f_0$, and

10

DETAILED DESCRIPTION OF THE INVENTION.

The invention will now be described by reference to the preferred embodiments. This does not intend to limit the scope
15 of the present invention, but to exemplify the invention.

Before discussing embodiments, a clearer description will be given of the object. Take a game, for example, in which CG rendering and other drawing processes are designed to complete within a frame period. Hereinafter, tasks that must complete
20 their processing within a predetermined period of time as above will be referred to as "real-time tasks." Tasks that have no time limit as if real-time tasks do will hereinafter be referred to as "non-real-time tasks." When these two types of tasks having different design concepts regarding the time
25 are executed in parallel, the real-timeness of the real-time

tasks depends greatly on the processing time of the non-real-time tasks.

Fig. 1A is a diagram showing in a time-series fashion the state of processing of tasks by a processor which operates at a normal operating frequency of f_0 . The periods from time T_0 to time T_1 , from time T_1 to time T_2 , and from time T_2 to time T_3 correspond to a single frame period each. In the diagram, a real-time task RT for drawing a frame and two non-real-time tasks NRT are executed by turns. Frames shall be displayed at times T_1 , T_2 , and T_3 . Between time T_0 and T_1 , a real-time task RT, a first non-real-time task NRT1, and a second non-real-time task NRT2 are executed in succession. Subsequently, the real-time task RT for drawing a frame to be displayed at time T_2 is executed, followed by the first non-real-time task NRT1 and the second non-real-time task NRT2 successively. Since the real-time tasks RT for displaying frames at times T_1 , T_2 , and T_3 complete their processing before respective times T_1 , T_2 , and T_3 , the frames are displayed without dropping.

Fig. 1B is a diagram showing in a time-series fashion the state of processing of tasks by the processor at an operating frequency of $0.8f_0$. For example, the operating frequency of the processor is adjusted to exercise heat control on the processor. The higher the processor temperature is, the lower the operating frequency is adjusted to be. When the operating frequency is lowered, the number of execute cycles of the

processor in a frame period decreases. This requires a longer time to complete each of the tasks. It follows that the real-time task RT, the first non-real-time task NRT1, and the second non-real-time task NRT2 to be executed in each frame period are executed in the subsequent frame period beyond the originally-intended frame period. In the diagram, the real-timeness of the real-time tasks RT is maintained substantially, whereas dropping frames can occur in the long run.

Fig. 1C is a diagram showing in a time-series fashion the state of processing of tasks by the processor at an operating frequency of $0.7f_0$. In the diagram, dropping frames occur immediately, failing to achieve game functions. As described above, when tasks are executed with a lower operating frequency in the same manner as with the normal operating frequency, it becomes difficult to guarantee the real-timeness of the real-time tasks.

Conventionally, computers have typically been used to run more or less a word processor program, an e-mail program, and the like in parallel, requiring not much attention to real-timeness of the tasks. In the meantime, game consoles even having general-purpose functions start to prevail, and the need for throttle technologies for lowering the operating frequency of a processor arises because of processor-heat problems. The inventor has thus reached the understanding of the foregoing problem of dropping frames in CG images, which

has not been in the past.

(Embodiment 1)

Embodiments 1 and 2 will deal with a non-preemptive task
5 management, or a task management method for situations where
tasks are switched autonomously. The task management method
according to embodiment 1 includes dividing a unit time of
processing into a reserved band for guaranteeing real-timeness
and a non-reserved band not for guaranteeing real-timeness,
10 and skipping tasks to be executed in the non-reserved band as
appropriate when processor throughput falls. That is, when the
operating frequency of the processor is lowered to suppress
heat generation, the real-timeness of tasks to be executed in
the reserved band is guaranteed at the expense of processing
15 the tasks to be executed in the non-reserved band in a best-
efforts fashion.

The "reserved band" is the number of execute cycles of
the processor to be guaranteed in unit time, and has a fixed
value. The "non-reserved band" is the number of execute cycles
20 of the processor not guaranteed in unit time, and has a
variable value in a predetermined range of 0 to a given value.
At the maximum processor throughput, the number of execute
cycles is the sum of the number of execute cycles in the
reserved band and the maximum number of execute cycles in the
25 non-reserved band. For example, when the operating frequency

of the processor is lowered for the sake of heat control, it is lowered so that variations in the number of execute cycles fall within the range of numbers of execute cycles available in the non-reserved band. Conversely, controlling the
5 operating frequency within this range guarantees the real-timeness of the tasks to be executed in the reserved band.

In the task management method according to embodiment 1, a mixture of real-time tasks and non-real-time tasks are executed with the real-time tasks assigned to the reserved
10 band and the non-real-time tasks the non-reserved band. For heat control, the operating frequency of the processor is controlled so that variations in the number of execute cycles due to the control of the operating frequency fall within the non-reserved band. Consequently, the control on the operating
15 frequency for the sake of heat control on the processor can be performed independent of the program design. That is, it is possible to exercise flexible heat control without limiting the degree of freedom of the program design. This makes it possible to make full use of the processor throughput while
20 changing the operating frequency for efficient heat control.

Fig. 2A is a diagram showing the state of execution of tasks at an operating frequency of f_0 , i.e., at the normal operating frequency where the heat generation of the processor need not be suppressed. With the operating frequency of f_0 ,
25 three tasks A, B, and C are executed in each single frame

period. The task A is a real-time task to be assigned to the reserved band. The tasks B and C are non-real-time tasks to be assigned to the non-reserved band.

Fig. 2B is a diagram showing the state of execution of tasks at an operating frequency of $0.7f_0$. The real-time tasks A2 and A3 complete their processing after times T2 and T3. This means a dropping frame.

Fig. 2C is a diagram showing the state of execution of tasks at the operating frequency of $0.7f_0$ where the tasks are managed based on the task management method according to the present embodiment. In the diagram, the non-real-time task C1 is skipped. Skipping non-real-time tasks as above advances the timing to execute subsequent real-time tasks. It is therefore possible to guarantee the real-timeness of the real-time tasks. More specifically, in the present embodiment, the reserved band is set at $0.7f_0$ and the non-reserved band at 0. The control of task management is thus switched across $0.7f_0$.

Fig. 3 is a block diagram of a processor system 10 which executes tasks by using the task management method described with reference to Fig. 2C. This processor system 10 is mounted on a game console. The processor system 10 includes a processor or semiconductor integrated circuit 100 and a main memory 14, which are connected to a bus 12. The bus 12 includes an address bus, a data bus, and a control bus. The semiconductor integrated circuit 100 has a main processing

unit 120, an internal clock generation unit 130, a task management unit 150, and a frequency control unit 110. The main memory 14 stores programs 16 to be executed by the semiconductor integrated circuit 100, and operation results 18 obtained through the execution of the respective programs 16. The programs 16 are read into the semiconductor integrated circuit 100 for task execution.

The semiconductor integrated circuit 100 includes not-shown circuits such as a cache memory, an instruction register, an arithmetic register, a decoder, a control unit, and an arithmetic unit, for example. Tasks are executed by using those circuits. Instructions stored in the cache memory or the main memory 14 are fetched and taken into the instruction register. The decoder decodes the instructions retained in the instruction register, and supplies control signals corresponding to the operation codes to the control unit. Based on the control signals, for example, the control unit selects arithmetic units for performing the processing corresponding to the operation codes, acquires data necessary for the operations from addresses designated by the operands, and writes the data to the operation register. The arithmetic units perform arithmetic processing by utilizing the data retained in the operation register, for example, and write to the addresses designated by the operands.

Note that Fig. 3 and subsequent diagrams show

configuration in units of function blocks, not in units of hardware components. The functional blocks need not be statically formed in the semiconductor integrated circuit 100 at the same time, but may be formed dynamically for a certain period of time. For example, in the present embodiment, the task management unit 150 and the frequency control unit 110 shall be dynamically formed in the semiconductor integrated circuit 100 by executing programs built in an operating system. The main processing unit 120 may originally be considered as the entire semiconductor integrated circuit 100 itself. For ease of understanding, however, the main processing unit 120 here shall refer to the functional parts excluding the frequency control unit 110, the internal clock generation unit 130, and the task management unit 150.

A base clock supply unit 30 supplies a base clock to the semiconductor integrated circuit 100. The internal clock generation unit 130 includes a PLL (Phase Locked Loop), for example, and generates a clock having a frequency several times that of the base clock. The clock generated by the internal clock generation unit 130 will be referred to as operating clock, and the frequency of the operating clock as operating frequency. The individual circuits included in the semiconductor integrated circuit 100 operate with the rising or falling timing of the operating clock. The internal clock generation unit 130 can change the operating frequency by

adjusting the counter value of a counter included in the circuits that constitute the PLL.

A temperature sensor 102 measures the temperature of the main processing unit 120 or a peripheral circuit thereof, and
5 outputs the measured temperature to the frequency control unit 110. The temperature sensor 102 may be formed outside the semiconductor integrated circuit 100, or inside the semiconductor integrated circuit 100, i.e., on the die.

The frequency control unit 110 determines an operating
10 frequency necessary for heat control in accordance with the temperature of the semiconductor integrated circuit 100. The frequency control unit 110 then controls the internal clock generation unit 130 to generate the operating clock having that frequency. When the temperature exceeds a predetermined
15 threshold, the frequency control unit 110 controls the internal clock generation unit 130 to lower the operating frequency. Lowering the operating frequency can suppress the amount of heat generated by the semiconductor integrated circuit 100. This can decrease the temperature of the
20 semiconductor integrated circuit 100 when combined with the action of heat radiation mechanisms such as a heat sink.

For heat control, the operating frequency is preferably adjusted so as not to sink below the reserved band. The operating frequency may be adjusted stepwise in accordance
25 with the temperature of the semiconductor integrated circuit

100. The frequency control unit 100 may lower the operating frequency below the reserved band, however, if there are not much tasks to execute or if an emergency is expected where the amount of heat generated by the semiconductor integrated circuit 100 is so large that the temperature cannot be lowered sufficiently within the non-reserved band alone. As above, various methods are available to control the operating frequency depending on the amount of heat generation. The frequency control unit 110 may determine the operating frequency based on any method.

For example, the frequency control unit 110 determines the operating frequency by referring to a table that contains temperatures and operating frequencies of the semiconductor integrated circuit 100 in association with each other. Then, the frequency control unit 110 makes the internal clock generation unit 130 generate the operating clock having that operating frequency.

The main processing unit 120 reads programs corresponding to tasks designated by the task management unit 150 from the main memory 14, and executes the tasks. The main processing unit 120 then writes operation results 18 obtained by executing the tasks to the main memory 14.

The task management unit 150 accepts frequency information for specifying the operating frequency of the main processing unit 120 from the frequency control unit 110, and

schedules tasks based on the information and in accordance with the task management method mentioned above.

Fig. 4 is an internal block diagram of the task management unit 150 of Fig. 3. A frequency detection unit 152
5 detects the operating frequency. In the present embodiment, the frequency detection unit 152 grasps the operating frequency by accepting the frequency information from the frequency control unit 110. The frequency detection unit 152 outputs the frequency information to a switch instruction unit
10 154.

The switch instruction unit 154 has a schedule creation unit 156 and an instruction unit 158, and issues instructions to switch tasks for the main processing unit 120 to execute. As will be detailed later, the schedule creation unit 156
15 consults a control target table 160 and a task table 164 to schedule tasks according to the operating frequency. Based on the schedule created by the schedule creation unit 156, the instruction unit 158 gives the main processing unit 120 instructions to execute the respective tasks.

20 Fig. 5 is a chart or graphical representation of data retained in the control target table 160 of Fig. 3. The control target table 160 holds the operating frequency and a control target, which determines how far to execute non-real-time tasks, in association with each other. This control
25 target shows the ratio of the number of non-real-time tasks

executed to the number of real-time tasks executed.

Hereinafter, this ratio will be referred to as "the rate of execution." When plotted on a graph with the operating frequency on the abscissa and the rate of execution of non-

5 real-time tasks on the ordinate, these pieces of data retained in the control target table 160 show different aspects across $0.7f_0$ as shown in this chart. In the present embodiment, the reserved band is set at $0.7f_0$. In the non-reserved band, or from f_0 to $0.9f_0$, non-real-time tasks have a rate of execution
10 of 100%. From $0.9f_0$ to $0.7f_0$, the rate of execution of non-real-time tasks decreases linearly from 100% to 10%. When the operating frequency falls below $0.7f_0$, or the reserved band, the rate of execution of non-real-time tasks is set at 10%. Below $0.7f_0$, the rate of execution of non-real-time tasks may
15 be set at 0% in order to guarantee the real-timeness of the real-time tasks. Nevertheless, the present embodiment employs the rate of execution of 10% so as to avoid such situations that non-real-time tasks are not executed at all. For example, a rate of execution of "30%" means that non-real-time tasks
20 are executed three times while real-time tasks ten times. Based on this control target, the schedule creation unit 156 of Fig. 3 adjusts the timing of execution of non-real-time tasks.

Fig. 6 is a diagram showing an example of the data
25 structure of the task table 164 in Fig. 4. The task table 164

has an attribute field 184, a task field 186, and a priority field 188 in association with each other. The attribute field 184 holds attribute information for indicating the attributes of tasks. In the present embodiment, the attributes are a
5 real-time task and a non-real-time task. In the diagram, "RT" represents a real-time task and "NRT" a non-real-time task. The task field 186 retains information for identifying tasks, such as the filename of a program and identification information on a task. For example, in the diagram, a
10 "rendering" task is registered as a real-time task. A "browser" task is registered as a non-real-time task. The priority field 188 retains information for indicating the priorities of the tasks. In the diagram, the priorities are shown on a scale of 1 to 10, where "10" is the highest in
15 priority and "1" the lowest in priority.

Returning to Fig. 4, when a user gives an instruction to execute a program, for example, a registration unit 162 interprets attribute information included in the program code. The registration unit 162 then registers the attribute
20 information in the task table 164 in association with information for identifying the program. If the program code does not contain any attribute information, the registration unit 162 registers the program in the task table 164 as a real-time task. This makes it possible to execute old programs
25 which contain no attribute information, for example.

In another example, the registration unit 162 may determine the properties of programs to be executed for respective tasks, estimate the attributes of the programs based on the determination, and register them in the task table 164. Here, the registration unit 162 estimates the attributes of the programs based on characteristics obtained indirectly through the execution of the tasks, such as instructions included in the programs and the rates and times of occupation of the processor by the programs. For example, in the case of non-preemptive task management, the registration unit 162 may measure the time of occupation of the processor in a certain period task by task, and estimate tasks of longer occupation times to be real-time tasks and ones of shorter occupation times to be non-real-time tasks. This makes it possible to perform appropriate task management even on programs that have no attribute information in their program codes.

Fig. 7 is an internal block diagram of the schedule creation unit 156 of Fig. 4. A first planning unit 170 consults the task table 164 and determines the order of execution of real-time tasks. When there are a plurality of real-time tasks, the first planning unit 170 refers to the priority field 188 of Fig. 6 and determines the order of execution so that real-time tasks having higher priorities come first. Then, the first planning unit 170 outputs the

order of execution of real-time tasks to an integration unit 178.

A second planning unit 172 consults the task table 164, determines the order of execution of non-real-time tasks, and
5 outputs the order of execution to the integration unit 178. The second planning unit 172 has a setting unit 174, a first counter 176a, and a second counter 176b. The first counter 176a and the second counter 176b will be referred to collectively as counters 176. The counters 176 count up each
10 time the processing for scheduling non-real-time tasks is performed, and give permission to execute non-real-time tasks at set rates.

For example, the first counter 176a is a counter for permitting the execution of non-real-time tasks at a rate of
15 25%. That is, permission to execute a non-real-time task is given once while real-time tasks are executed three times. The permission timing may be determined arbitrarily. The diagram shows the case where the first counter 176a has the permission timing of "oxxx". Since "o" indicates permission and "x" no
20 permission, the timing shows that the first counter 176a initially permits the execution of a non-real-time task before skipping three times.

The setting unit 174 accepts the current operating frequency from the frequency detection unit 152, and reads the
25 control target for non-real-time tasks corresponding to the

operating frequency from the control target table 160. Then,
the setting unit 174 sets the rate at which the counter 176
permit the execution of non-real-time tasks according to the
control target. For example, to execute 25% of non-real-time
5 tasks, the setting unit 174 sets the counter 176 so as to
permit the execution of non-real-time tasks every four times.

When there are a plurality of non-real-time tasks,
counters 176 are provided as many as the non-real-time tasks.
The setting unit 174 then sets the counters 176 so that the
10 total number of execution of the plurality of non-real-time
tasks coincides with the control target. Suppose, for example,
that there are two non-real-time tasks, and the non-real-time
tasks are executed at a rate of 25%. In this case, the setting
unit 174 sets each of the first counter 176a and the second
15 counter 176b to permit the execution of a non-real-time task
once while real-time tasks are executed eight times. Moreover,
the setting unit 174 sets the permission timing so that the
two non-real-time tasks are executed at different timing. For
example, the first counter 176a is given the permission timing
20 of "xxxxxxxx" and the second counter 176b the permission
timing of "xxxxxxox".

Moreover, when non-real-time tasks are executed at a rate
of 50%, for example, the setting unit 174 sets such permission
timing as "oxox" with discrete "o"s and "x"s, not "ooxx". That
25 is, the permission timing is set so that non-real-time tasks

are permitted to be executed at distributed timing.

Distributing the timing to permit the execution of non-real-time tasks as above gives the non-real-time tasks a smoother feel.

5 The integration unit 178 creates a schedule by arranging the order of execution of real-time tasks supplied from the first planning unit 170 and the order of execution of non-real-time tasks supplied from the second planning unit 172 so that the order of execution of real-time tasks comes first.

10 The integration unit 178 then outputs the created schedule to the instruction unit 158.

Fig. 8 is a flowchart of the processing by which the task management unit 150 of Fig. 4 schedules tasks. The frequency detection unit 152 of Fig. 4 detects the operating frequency (S10). The schedule creation unit 156 of Fig. 4 consults the control target table 160 of Fig. 4 based on the operating frequency, and schedules the order of execution of real-time tasks and non-real-time tasks (S12). The instruction unit 158 of Fig. 4 issues instructions to execute tasks in the order scheduled by the schedule creation unit 156 (S14).

15

20

(Embodiment 2)

Fig. 9 is an internal block diagram of the task management unit 150 according to embodiment 2. Embodiment 2 is one in which the control target table 160 is optimized

25

according to the usage rate of the semiconductor integrated circuit 100. In the diagram, components having generally the same functions and operations as those of components described previously will be designated by identical reference numerals to those of the components described previously. The following description will deal chiefly with differences from the functions of the components described previously.

A processor usage rate detection unit 190 detects the usage rate of the semiconductor integrated circuit 100 of Fig.

3, for example, in every frame period. The processor usage rate detection unit 190 then outputs the usage rate to an update unit 192. The update unit 192 calculates an average usage rate over a predetermined period. Based on the average, the update unit 192 optimizes the control target table 160 so as to increase the rate of execution of non-real-time tasks. For example, the update unit 192 calculates an average usage rate over 0.5 seconds, i.e., 30 frames. If the average is lower than a threshold, or equivalently, if the load is relatively low, the update unit 192 increases the rate of execution of non-real-time tasks in the control target table 160. If the average is higher than the threshold, the update unit 192 restores the control target table to its default. The threshold and the range of increase in the rate of execution of non-real-time tasks may be set appropriately by experiments, or adjusted gradually through execution.

Fig. 10 is a chart or graphical representation of data retained in the control target table 160, optimized by the update unit 192 of Fig. 9. In this chart, the reserved band is shifted to $0.5f_0$. From $0.9f_0$ to $0.5f_0$, the rate of execution of non-real-time tasks is decreased linearly from 100% to 10%. When the reserved band is thus adjusted according to the usage rate of the processor, it is possible to make effective use of the processor throughput.

Fig. 11 is a flowchart of the processing by which the task management unit 150 of Fig. 9 schedules tasks. The scheduling processing in the task management unit 150 of Fig. 9 is achieved by adding the processing for optimizing the control target table (S20) to the scheduling processing of the task management unit 150 of Fig. 4 which has been described with reference to Fig. 8.

Fig. 12 is a detailed flowchart of the processing for optimizing the target control table of Fig. 11 (S20). The processor usage rate detection unit 190 of Fig. 9 detects the usage rate of the semiconductor integrated circuit 100 of Fig. 3 (S22). The update unit 192 of Fig. 9 determines whether or not a predetermined period has elapsed (S24). If the predetermined period has elapsed (Y at S24), the update unit 192 calculates the average usage rate in that period (S26). Then, if the usage rate is higher than a predetermined threshold (Y at S28), the control target table is restored to

its default (S34). At step 28, if the usage rate is lower than the predetermined threshold (N at S28), the update unit 192 modifies the control target table so as to increase the rate of execution of non-real-time tasks (S30). At step 24, if the predetermined period has not elapsed yet (N at S24), the processing moves to step 10 of Fig. 11. As above, since the control target table 160 is optimized according to the usage rate of the main processing unit 120, it is possible to maximize the throughput of the main processing unit 120.

10

(Embodiment 3)

Embodiments 3 and 4 will deal with a preemptive task management, or a task management method for situations where tasks are forcibly switched by timer interruptions.

15

Hereinafter, a frame period will be denoted as "t". In the task management method according to embodiment 3, non-real-time tasks are executed in a period that is allocated as a non-reserved band. Hereinafter, a period that is allocated as a reserved band will be referred to as "reserved period t_r ," and a period that is allocated as a non-reserved band will be referred to as "non-reserved period t_n ." If there are a plurality of non-real-time tasks, the non-reserved period t_n is divided into equal parts in which the respective non-real-time tasks are executed.

20

25

Fig. 13A is a diagram showing the state of execution of

tasks at an operating frequency of f_0 . When the operating frequency is f_0 , the reserved period t_r is set at $0.7t$ and the non-reserved period t_n $0.3t$. Since there are two non-real-time tasks, the non-real-time tasks are executed in succession over
5 a period of $0.15t$ each.

Fig. 13B is a diagram showing the state of execution of tasks at an operating frequency of $0.8f_0$. When the operating frequency is $0.8f_0$, the period equivalent to the operating frequency is $t / (0.8 \cdot f_0)$. The reserved period t_r is thus
10 $0.7f_0 \cdot t / (0.8 \cdot f_0) = 7/8 \cdot t$, and the non-reserved period t_n is $1/8 \cdot t$. Since there are two non-real-time tasks, the non-real-time tasks are executed in succession over a period of $1/16 \cdot t$ each. In the diagram, the reserved period t_r is occupied by the real-time task RT. Nevertheless, since the program of the
15 real-time task RT is designed to complete processing within a period shorter than the reserved period t_r , it is typically rare for the reserved period t_r to be fully occupied.

Fig. 14 is a diagram showing an example of the internal block diagram of the task management unit 150 according to
20 embodiment 3. In the diagram, components having generally the same functions and operations as those of components described previously will be designated by identical reference numerals to those of the components described previously. The following description will deal chiefly with differences from the
25 functions of the components described previously. The schedule

creation unit 156 schedules tasks in the manner as described with reference to Fig. 13. The schedule creation unit 156 reads real-time tasks and non-real-time tasks from the task table 164, and creates a schedule so that the real-time tasks are executed before the non-real-time tasks. For the sake of scheduling, the schedule creation unit 156 also consults the control target table 160 to determine the execution times of the non-real-time tasks corresponding to the operating frequency. Then, the schedule creation unit 156 creates the schedule, for example, so that the non-real-time tasks are associated with their respective execution times. Based on the execution times included in the schedule, the instruction unit 158 sets an interrupt timer for switching the non-real-time tasks.

Fig. 15 is a chart or graphical representation of data retained in the control target table 160 of Fig. 14. The control target table 160 retains the operating frequency and the time for which the processor can be occupied to execute non-real-time tasks, i.e., the non-reserved period t_n in association with each other. When plotted on a graph with the operating frequency on the abscissa and the non-reserved period t_n on the ordinate, these pieces of data retained in the control target table 160 show different aspects across $0.7f_0$ as shown in this chart. In the present embodiment, the reserved band is set at $0.7f_0$. In the non-reserved band, or

from f_0 to $0.9f_0$, the non-reserved period t_n is $0.3t$. From $0.9f_0$ to $0.7f_0$, the non-reserved period t_n decreases linearly from $0.3t$ to $0.01t$. When the operating frequency falls below the reserved band of $0.7f_0$, the non-reserved period t_n is set at $0.01t$. Below $0.7f_0$, the non-reserved period t_n may be set at 0 in order to guarantee the real-timeness of the real-time tasks. Nevertheless, the present embodiment employs a non-reserved period t_n of $0.01t$ so as to avoid such situations that non-real-time tasks are not executed at all. For example, if the non-reserved period t_n is " $0.1t$ " and there are two non-real-time tasks, each of the non-real-time tasks has an execution time of $0.05t$. Based on this control target, the schedule creation unit 156 of Fig. 14 adjusts the execution time of the non-real-time tasks.

15

(Embodiment 4)

Fig. 16 is an internal block diagram of the task management unit 150 according to embodiment 4. Embodiment 4 is one in which the control target table 160 is optimized according to the usage rate of the semiconductor integrated circuit 100. In the diagram, components having generally the same functions and operations as those of components described previously will be designated by identical reference numerals to those of the components described previously. The following description will deal chiefly with differences from the

25

functions of the components described previously.

The update unit 192 calculates an average usage rate of the semiconductor integrated circuit 100 in a predetermined period. Based on the average, the update unit 192 optimizes
5 the control target table 160 so as to increase the non-reserved period t_n . If the average is lower than a threshold, or equivalently, if the load is relatively low, the update unit 192 increases the non-reserved period t_n of the control target table 160. If the average is higher than the threshold,
10 the update unit 192 restores the control target table to its default. The threshold to be used for the update determination and the range of increase of the non-reserved period t_n may be set as appropriate by experiments, or adjusted gradually through execution.

15 Fig. 17 is a chart or graphical representation of data retained in the control target table 160, optimized by the update unit 192 of Fig. 16. In this chart, the reserved band is shifted to $0.5f_0$. From $0.9f_0$ to $0.5f_0$, the non-reserved period t_n decreases linearly from $0.3t$ to $0.01t$. When the
20 reserved band is thus adjusted according to the usage rate of the processor, it is possible to make effective use of the processor throughput.

Up to this point, the present invention has been described in conjunction with the embodiments thereof. These
25 embodiments have been given solely by way of illustration. It

will be understood by those skilled in the art that various modifications may be made to combinations of the foregoing components and processes, and all such modifications are also intended to fall within the scope of the present invention.

5 Embodiments 1 to 4 have dealt with the cases where tasks having such time limits that their drawing processing must be completed within a single frame period are allocated to the reserved band, and tasks having no time limit are allocated to the non-reserved band. In a modification, however, the
10 condition for allocation between the reserved period and the non-reserved period is not necessarily limited thereto.

Tasks may be allocated to the reserved band or the non-reserved band depending on aspects other than time limits. For example, tasks may be allocated to either of the reserved band
15 and the non-reserved band depending on whether the data must be recorded with reliability or not. For instance, if there are a task for recording a broadcast program and a task of a word processor, the recording task may be allocated to the reserved band and the word-processor task for the non-reserved
20 band in view of reliable data recording. As above, the condition for allocation between the reserved band and the non-reserved band can be changed to adopt the task management methods described in the embodiments, for example, into electronic apparatuses having a real-time OS installed therein,
25 such as an aircraft control computer and an automobile control

computer.

The embodiments have dealt with the cases where the operating frequency of the semiconductor integrated circuit 100 is controlled in view of heat control. In another
5 modification, the operating frequency may be controlled in view of power consumption. The power consumption is proportional to the operating frequency of the clock, the number of transistors in the circuits, and the square of the power supply voltage. Conversely, if the operating frequency,
10 the number of load transistors, and the power supply voltage are known, it is possible to calculate the power consumption. For example, the frequency control unit 110 of Fig. 3 may acquire a voltage value from a sensor for measuring the output voltage of a regulator. The operating frequency is then
15 lowered to avoid thermal runaway when the power consumption calculated from the voltage value exceeds a predetermined threshold. Moreover, if it is judged whether the power supply is in battery mode or AC supply mode, and found to be in the battery mode, the operating frequency may be lowered for the
20 sake of power saving. Even in these cases, the task management methods described in the embodiments can be used to guarantee real-time tasks' real-timeness.

The embodiments have dealt with the cases where the rate of execution of non-real-time tasks is adjusted in accordance
25 with the operating frequency of the main processing unit 120.

In another modification, the rate of execution of non-real-time tasks may be adjusted in accordance with the temperature of the main processing unit 120 or a peripheral circuit thereof. Suppose, for example, that there is a circuit for
5 controlling the operating frequency of the clock to be supplied to the main processing unit 120 according to the temperature of the main processing unit 120 or a peripheral circuit thereof independently of software. Then, the operating frequency is controlled in accordance with the temperature of
10 the main processing unit 120 or the peripheral circuit by hardware means. When such a circuit cannot acquire by software means the frequency information but the temperature information, i.e., when the task management unit 150 of Fig. 3 cannot acquire the frequency information but the temperature
15 information, the rate of execution of tasks may be adjusted based on the temperature information. In this case, the control target table 160 of Fig. 4 retains, for example, the temperature of the main processing unit 120 or the peripheral circuit thereof and the rate of execution in association with
20 each other. Based on this table, the schedule creation unit 156 of Fig. 4 then adjusts the timing to execute non-real-time tasks.

The rate of execution of non-real-time tasks may also be adjusted in accordance with the power consumption of the main
25 processing unit 120 or the semiconductor integrated circuit

100. When the task management unit 150 of Fig. 3 cannot
acquire the frequency information but power consumption
information from various types of power management programs or
the like, the rate of execution of tasks may be adjusted based
5 on the power consumption information. In this case, the
control target table 160 of Fig. 4 retains, for example, the
power consumption information and the rate of execution in
association with each other. Based on this table, the schedule
creation unit 156 of Fig. 4 then adjusts the timing to execute
10 non-real-time tasks.

The present invention is applicable to the field of task
management of a processor.
